CHEMICAL PULP FROM KENAF BY KRAFT AND POLYSULPHIDE PROCESSES

By Chien Chu*, Naiyana Niyomwan*, and Anchalee Puangvichit*

SUMMARY

Bleached kraft pulps were prepared from Cuban kenaf (Hibiscus cannabinus) and Thai kenaf (Hibiscus sabdariffa) by two modified kraft processes. One was polysulphide process. It gave higher yield of pulp than conventional kraft process. Cooking yields about 50% on chip weight were obtained from both Cuban kenaf and Thai kenaf by cooking at 170°C for 1½ hours. The polysulphide pulps with permanganate no. about 20 were bleached by DC/E/D sequence with about 8 to 9% equivalent chlorine to brightness 75-87%. The strength of bleached kenaf polysulphide pulps and kraft pulps was comparable to softwood bleached kraft pulp except for bursting strength.

The other modified kraft process was alkaline pretreatment with about 2% sodium sulphide on chip weight at 110-120°C for 30-60 minutes before alkaline pulping by soda, kraft, or polysulphide process at 170°C for 60-90 minutes. The pretreatment improved bleachability and strength of the pulps.

INTRODUCTION

Kraft process is the most widely used process for production of wood pulp. The process is distinguished for its high pulp strength but low yield, dark colour, and high bleach consumption. Thus paper from kraft wood pulp is usually used for industrial packaging and no bleaching is required for such purpose. With the advent of modern chlorine dioxide bleaching, bleached kraft wood pulp by multistage bleaching has attained high brightness with good strength.

Clark et al. (1962) reported pulping of Cuban kenaf by kraft process and compared that by neutral sulphite process and soda process. The kraft pulping of air-dry Cuban kenaf (H. cannabinus) with 16-19%

*Chemical Technology Group, Technological Research Institute, ASRCT.

Na_2O with liquor ratio 6:1 indicated good strength but high bleach consumption (Clark and Wolff 1965).

Monsalud et al. (1965) worked on kraft pulping of Cuban kenaf with 15-18% NaOH and 5-6% Na_2S , showing good strength quality with unbleached yield about 42-46%. But no bleaching result was reported.

Kraft pulping of Thai kenaf (H. sabdariffa) has not yet been recorded in the literature. Hence this study was made to compare kraft pulping with both Thai and Cuban kenaf and to explore modifications of standard kraft process for higher yield and better bleachability.

One modified kraft process employs two-stage pulping with or without washing between the two stages. The process is aimed at reducing bleach consumption.

Another modified kraft process is the polysulphide process, which reduces alkaline hydrolysis of hemicellulose and provides a higher yield (Clayton and Sakai 1969).

A third modified kraft process involves pretreatment of wood chips with H_2S gas under pressure for a short time before standard kraft pulping for higher yield. Commercial development of this process has not yet been reported (Vinje and Worster 1969).

In standard kraft process the chemicals used in cooking are caustic soda and sodium sulphide. These chemicals are recovered by the recovery system as soda ash and sodium sulphide. In polysulphide pulping, the recovered chemicals from chemical recovery system are also sodium sulphide and sodium carbonate in the green liquor. The polysulphide can be produced from sodium sulphide by oxidation of sodium sulphide in the green liquor with manganese dioxide (Barker 1970). Thus the study of kraft process for kenaf was extended to include these new developments in respect to regeneration of polysulphides in a kraft recovery system.

EXPERIMENTAL

Fresh and air-dry kenaf stalks were shredded into small chips about 2 cm long. Cooking and bleaching conditions are shown in Table 1.

For standard kraft process, only caustic soda and sodium sulphide were used in one-stage or two-stage cooking. The two-stage process had sodium sulphide cooking in the first stage followed by caustic soda cooking in the second stage with or without any sodium sulphide. In most cases, no washing was made between the two stages. However, several experiments had washing between the stages.

For polysulphide process, the cooking liquor was prepared with the addition of sulphur at 60-80°C for $\frac{1}{2}$ hour to the sodium sulphide kraft liquor with or without caustic soda to form polysulphides. The polysulphide kraft liquor had an orange colour as compared with the greenish colour of standard kraft liquor containing sodium sulphide and caustic soda.

In one-stage polysulphide pulping, all the caustic soda required for pulping was contained in the cooking liquor, whereas in the two-stage cooking most of the caustic soda for pulping was applied in the second stage. The two-stage polysulphide process as indicated in cooks nos. 403, 366, and 428 was intended to avoid excessive alkalinity at the start of pulping for higher yield and better bleachability.

Instead of adding sulphur to sodium sulphide solution to make polysulphides as described above, technical grade manganese dioxide containing about 80% MnO_2 was reacted with sodium sulphide kraft liquor, with or without caustic soda, at 70-80°C for $\frac{1}{2}$ hour to effect oxidation of sodium sulphide in the solution to polysulphide. The following equation indicates the reaction (Barker 1970):

The hot polysulphide liquor was cooled and filtered to remove the manganese dioxide residue, which was oven-dried to regenerate the MnO_2 and reused in many cycles. About 16 cycles of manganese dioxide

oxidation of sodium sulphide liquor were tried without any appreciable loss of yields. The sulphidity of the solution before oxidation to polysulphides was about 30-50% or 5-12% Na_2S with 0-18% NaOH . One example was cook no. 463 for MnO_2 oxidation of kraft liquor containing 9% Na_2S and 15% NaOH .

Also to avoid the high sulphidity before polysulphide conversion by MnO_2 oxidation, sulphur was added after the MnO_2 oxidation and filtration to remove the MnO_2 residue. The sulphur added amounted to about 1-2% on chip weight, which is about half the amount usually required for equivalent make-up as salt cake in the kraft recovery system. Cook no. 444 is an example featuring 10% Na_2S and 15% NaOH in kraft liquor before MnO_2 oxidation to polysulphide and then 1% sulphur was added to the polysulphide liquor to form more polysulphides.

As reported in the pulping of kenaf by soda process, pretreatment of kenaf chips before cooking with dilute sodium sulphide solution improved bleachability. Cook no. 457 for polysulphide process was preceded by pretreatment with dilute sodium sulphide solution containing about 2% Na_2S on chip weight. The sulphide solution was prepared from waste sodium sulphide liquor from Summit Petroleum Refinery. The chips were treated in the solution at 120°C for 45 minutes. The waste liquor was drained and the chips were washed. The treated chips were cooked with the polysulphide cooking liquor prepared by MnO_2 oxidation of a kraft liquor containing 10% Na_2S and 15% NaOH . The cooking conditions were impregnation at 110°C for 45 minutes and cooking at 170°C for 60 minutes.

The simplest bleaching sequence was the 3-stage C/E/H sequence as shown by the bleaching of polysulphide kraft pulp from cook no. 457 with 7% chlorine. In this case, the chlorination (C) was done in 3% pulp consistency at room temperature about $30-35^\circ\text{C}$ for $\frac{1}{2}$ hour with 5% chlorine from acidified sodium hypochlorite solution at pH 1.8. The chlorinated pulp was washed. The caustic extraction (E) was done at 10% pulp consistency at 70°C for $\frac{1}{2}$ hour. The extraction solution contained 2% NaOH on pulp weight. The hypochlorite bleaching (H) was carried out at 40°C for 3 hours in sodium hypochlorite solution containing 2% available chlorine on pulp weight. A final acid wash with

0.2% SO_2 on pulp weight in sulphurous acid solution at 30°C for $\frac{1}{2}$ hour completed the bleaching process.

The bleaching of pulp for cook no. 366 was performed also in three stages C/EP/H sequence but with peroxide bleaching included in the caustic extraction stage. The chlorination (C) was the same as the above example but with 8% chlorine. The second stage (EP) was a combination of alkali extraction and peroxide bleaching at 10% pulp consistency and 70°C for 2 hours with 1% sodium peroxide on pulp weight. The peroxide solution was buffered with 5% sodium silicate and 0.2% magnesium sulphate. The third bleaching stage was hypochlorite bleaching (H) with 2% available chlorine in the same way as the above example.

The bleaching procedures in other experiments were more elaborate, featuring ClO_2 in chlorination stage, and followed essentially the same way as previously described in this series of study on kenaf pulps by soda process and bisulphide process. The details of bleaching sequences are shown in Table 1.

RESULTS AND DISCUSSION

Table 1 shows data of all experimental results of pulping, bleaching, and physical tests. Tables 2 and 3 compare the various pulps made by several processes and raw materials. From Table 2, it appears that the polysulphide process gave the best yield and strength. From Table 3, kenaf polysulphide pulp compares favourably in pulp strength with most other pulps, except for tearing strength of Pinus merkusii pulp and Casuarina equisetifolia pulp.

The kraft pulp from kenaf by the conventional process had good strength but rather low yield as indicated in cook no. 494. The yield was improved by the two-stage kraft process as indicated in cooks nos. 502, 490, 488, and 329.

The polysulphide process appears effective for higher yield when compared with that by conventional kraft process. Chemical application was slightly higher due to the additional sulphur needed for the formation of polysulphides; otherwise it requires a high sulphidity above 25% for manganese dioxide oxidation of the sulphide into polysulphides. The amount of polysulphide sulphur needed for the high yield of pulp was about 4-6% on chips. This was compensated by the higher pulp yield, about 6-8% on chips above the yield by conventional kraft process.

Chemical recovery system for the polysulphide process is essentially the same as that for conventional kraft process, except for additional treatment of the green liquor or white liquor to convert the sodium sulphide in the liquor into polysulphides. This can be done either by adding sulphur to the green liquor or by manganese dioxide oxidation of the green liquor. A combination of manganese dioxide oxidation and sulphur addition is also applicable. This combination can reduce the amount of sulphur in the polysulphide conversion to the level of about 1-2% which is usually used as make-up in conventional kraft recovery system.

Several experiments in polysulphide pulping applied about 4-5% sulphur for reacting with sodium sulphide to make polysulphides. In the chemical recovery system with the polysulphide process, the sulphur loss as SO_2 in the flue gas of the recovery boiler will be higher than

that in the conventional kraft process. Recovery of this SO_2 in flue gas with soda ash solution to make neutral sulphite solution or bisulphite solution may ^{be} applicable if the kraft mill has also neutral sulphite (NSSC) pulp or bisulphite pulp production.

The recovery of chemicals from two-stage kraft and two-stage polysulphide processes calls for separation of sodium sulphide from soda in the green liquor of kraft recovery system by fractional crystallization of soda as monohydrate from clarified green liquor. Although this is a little more complicated, it may have some advantages, especially if the kraft mill has also NSSC pulp or bisulphite pulp production.

If waste sodium sulphide effluent from petroleum refinery is available to the pulp industry at low cost, the kraft pulp mill may use this waste effluent for pretreatment at $100\text{--}120^\circ\text{C}$ for 45-60 minutes. The waste liquor may be discarded, and the treated chips are washed and pressed for subsequent cooking with caustic soda with or without additional sodium sulphide. The black liquor from cooking can be recovered in the normal way used in conventional kraft process. As indicated in cooks nos. 456 and 457, the pulps have high bleached yield and good bleachability. As indicated in cooks nos. 456, 490, and 502, two-stage kraft pulping gave improved bleachability and better strength. This was also true with one-stage polysulphide pulping following alkaline pretreatment. Cooks nos. 455 and 457 compared the results of pretreatment for the two processes. Yield and strength were significantly better for the polysulphide pulping with alkaline pretreatment.

As indicated in cook no. 471, polysulphide pulping with pretreatment resulted in high yield and good bleachability. However, the disposal of waste effluent from the pretreatment stage must be properly made to avoid pollution.

Cooks nos. 536, 553, 513, 515, 516, and 517 were high-temperature short-time polysulphide pulping at 175° for 25-30 minutes. They showed little advantage on pulp yield when compared with cook no. 552 for conventional kraft pulping at high temperature of 175°C for 25 minutes; but pulp strength appeared better with the polysulphide process as indicated in cook no. 515 for Cuban kenaf.

CONCLUSIONS

1. Pulping Cuban kenaf and Thai kenaf by standard kraft process with 15-18% Na_2O and sulphidity 10-15% gets cooking yield 42-43% for air-dry kenaf and 45-46% for fresh Cuban kenaf. The cooking conditions applied are heating to a maximum temperature of 170°C in $1\frac{1}{2}$ hours and cooking at the maximum temperature (170°C) for $1\frac{1}{2}$ -2 hours.

The pulp from fresh kenaf has better bleachability requiring 8% chlorine for 80% brightness, whereas pulp from dry kenaf needs about 9% chlorine in DC/E/D bleaching sequence for brightness above 80%.

2. Polysulphide process can be applied for pulping kenaf at about 170°C for higher yield of pulp with better strength. The cooking liquor can be prepared by adding sulphur to the standard kraft liquor to form polysulphides or by oxidation of standard kraft liquor of high sulphidity at 25-50% with about 12% manganese dioxide on chips. The spent manganese dioxide can be regenerated by air oxidation when dried. A combination of MnO_2 oxidation and sulphur addition for preparation of polysulphide from kraft liquor is also applicable for higher polysulphides content.

3. At higher temperature of 175°C and short time cooking for 25-30 minutes, the advantages of polysulphide over kraft process are not significant in respect to pulp yield.

4. Alkaline pretreatment with dilute sodium sulphide (about 2-3% on pulp weight) before kraft or polysulphide pulping improves bleachability and pulp strength. This applies also to two-stage kraft pulping with advantages of both higher yield and better bleachability.

ACKNOWLEDGEMENT

We wish to express our sincere thanks to the Royal Forest Department for the use of their laboratory facilities for part of the work in this project.
